**Abstract :** Given a configuration of pebbles on the vertices of a connected graph  $G$ , a pebbling move (or pebbling step) is defined as the removal of two pebbles from a vertex and placing one pebble on an adjacent vertex. The domination cover pebbling number,  $\psi(G)$ , of a graph  $G$  is the minimum number of pebbles that are placed on  $V(G)$  such that after a sequence of pebbling moves, the set of vertices with pebbles forms a dominating set of  $G$ , regardless of the initial configuration. In this paper, we determine  $\psi(G)$  for odd cycle lollipop.

**Keywords :** Pebbling, Cover pebbling, Domination cover pebbling, Lollipop.

## 1. Introduction

One recent development in graph theory, suggested by Lagarias and Saks, called pebbling, has been the subject of much research. It was first introduced into the literature by Chung [1], and has been developed by many others including Hulbert, who published a survey of graph pebbling [5]. There have been many developments since Hulbert's survey appeared.

Given a graph  $G$ , distribute  $k$  pebbles (indistinguishable markers) on its vertices in some configuration  $C$ . Specifically, a configuration on a graph  $G$  is a function from  $V(G)$  to  $\mathbb{N} \cup \{0\}$  representing an arrangement of pebbles on  $G$ . For our purposes, we will always assume that  $G$  is connected. A pebbling move (or pebbling step) is defined as the removal of two pebbles from some vertex and the placement of one of these pebbles on an adjacent vertex. Define the pebbling number,  $\pi(G)$ , to be the minimum number of pebbles such that regardless of their initial configuration, it is possible to move to any root vertex  $v$ , a pebble by a sequence of pebbling moves. Implicit in this definition is the fact that if after moving to vertex  $v$  one desires to move to another root vertex, the pebbles reset to their original configuration.

The domination cover pebbling [3] is the combination of two ideas cover pebbling [2] and domination [4]. This introduces a new graph invariant called the domination cover pebbling number,  $\psi(G)$ . Recall that, a set of vertices  $D$  in  $G$  is a dominating set if every vertex in  $G$  is either in  $D$  or adjacent to a vertex of  $D$ . The cover pebbling number,  $\lambda(G)$ , is defined as the minimum number of pebbles required such that given any initial configuration of at least  $\lambda(G)$  pebbles, it is possible to make a series of pebbling moves to place at least one pebble on every vertex of  $G$ . The domination cover pebbling number of a graph  $G$ , proposed by A. Teguia, is the minimum number  $\psi(G)$  of pebbles required such that any initial configuration of at least  $\psi(G)$  pebbles can be transformed so that the set of vertices that contain pebbles form a dominating set of  $G$ . We have determined the domination cover pebbling number of the square of a path in [7]. In section 2, we determine the domination cover pebbling number for odd cycle lollipop. For this we use the following theorems:

**Theorem 1.1**[3] For  $n \geq 3$ ,  $\psi(P_n) = 2^{n+1} \left( \frac{1 - 8^{-(\beta_n+1)}}{7} \right) + \left\lfloor \frac{\alpha_n}{2} \right\rfloor$ , where

$$n - 2 = \alpha_n + 3\beta_n \equiv \alpha_n \pmod{3}.$$

■

■  $-2 = \alpha_n + 3\beta_n \equiv \alpha_n \pmod{3}$ . ■

From this theorem, we can derive the following :

From this theorem, we can derive the following :

From this theorem, we can derive the following :

$$\psi(P_n) = \begin{cases} \frac{2^{n+1}-1}{7}, & \text{if } \alpha_n \equiv 0 \\ \frac{2^{n+1}-2}{7}, & \text{if } \alpha_n \equiv 1 \\ \frac{2^{n+1}+3}{7}, & \text{if } \alpha_n \equiv 2 \end{cases}$$

Also, from this we have,  
Also, from this we have,

$$\frac{2^{n+1}-2}{7} \leq \psi(P_n) \leq \frac{2^{n+1}+3}{7}$$

**Theorem 1.2**[3] Let  $C_m$  be a cycle on  $m$  vertices. Then the domination cover pebbling number is given by,

**Theorem 1.2**[3] Let  $C_m$  be a cycle on  $m$  vertices. Then the domination cover pebbling

$$\psi(C_m) = \begin{cases} \psi(P_k) + \psi(P_{k-1}) - |\alpha_k - 1| |\alpha_{k-1} - 1|, & \text{if } m = 2k - 2 (k \geq 3) \\ 2\psi(P_k) - |\alpha_k - 1|, & \text{if } m = 2k - 1 (k \geq 2) \\ \psi(P_k) + \psi(P_{k-1}) - |\alpha_k - 1| |\alpha_{k-1} - 1|, & \text{if } m = 2k - 2 (k \geq 3) \end{cases}$$

where  $k - 2 \equiv \alpha_k \pmod{3}$  and  $(k - 1) - 2 \equiv \alpha_{k-1} \pmod{3}$ . ■

where  $k - 2 \equiv \alpha_k \pmod{3}$  and  $(k - 1) - 2 \equiv \alpha_{k-1} \pmod{3}$ .

**2 Domination cover pebbling number for odd cycle lollipop**  
**Domination cover pebbling number for odd cycle lollipop**

**Definition 2.1** [6] For a pair of integers  $m \geq 3$  and  $n \geq 2$ , let  $L(m, n)$  be the lollipop graph of order  $n+m-1$  obtained from a cycle  $C_m$  by attaching a path of length  $n-1$  to a vertex of the cycle.

We will use the following labeling for the graphs  $C_m$  and  $P_n$ .  
 We will use the following labeling for the graphs  $C_m$  and  $P_n$ .

We will use the following labeling for the graphs  $C_m$  and  $P_n$ .

$$C_m: v_0 v_1 v_2 \dots v_{m-1} v_0 \quad (m \geq 3) \text{ and } P_n: v_0 v_{p_1} v_{p_2} \dots v_{p_{n-1}} \quad \begin{matrix} (n \geq 2) \\ (n \geq 2) \end{matrix}$$

If the cycle  $C_m$  in  $L(m,n)$  is odd, then  $L(m,n)$  is called odd cycle lollipop. Now, we proceed to find the domination cover pebbling number for  $L(3,n)$ , where  $n \geq 2$ .  
 If the cycle  $C_m$  in  $L(m,n)$  is even, then  $L(m,n)$  is called even cycle lollipop. Now, we proceed to find the domination cover pebbling number for  $L(3,n)$ , where  $n \geq 2$ .

**Theorem 2.2** Let  $L(3,2)$  be a lollipop graph. Then  $\psi(L(3,2))=3$ .  
**Theorem 2.2** Let  $L(3,2)$  be a lollipop graph. Then  $\psi(L(3,2))=3$ .

**Proof:** Consider the graph  $L(3,2)$ . Put one pebble each on both  $v_1$  and  $v_2$ . Clearly, we cannot cover dominate the vertex  $v_0$ . Thus,  $\psi(L(3,2)) \geq 3$ .  
**Proof:** Consider the graph  $L(3,2)$ . Put one pebble each on both  $v_1$  and  $v_2$ . Clearly, we cannot cover dominate the vertex  $v_{p_1}$ . Thus,  $\psi(L(3,2)) \geq 3$ .

Now, consider the distribution of three pebbles on the vertices of  $L(3,2)$ .  
 Now, consider the distribution of three pebbles on the vertices of  $L(3,2)$ .

**Case1:**  $C_3$  contains at least one pebble.  
**Case1:**  $C_3$  contains at least one pebble.

If  $v_0$  contains one or more pebbles then we are done, since  $\psi(C_3)=1$ . So, assume that  $v_0$  contains zero pebbles. This implies that  $C_3$  contains all the three pebbles. Clearly, we are done if  $v_0$  contains a pebble. Otherwise either  $v_1$  or  $v_2$  contains at least two pebbles. From this we can send one pebble to  $v_0$  and we are done.  
 If  $v_{p_1}$  contains one or more pebbles then we are done, since  $\psi(C_3)=1$ . So, assume that  $v_{p_1}$  contains zero pebbles. This implies that  $C_3$  contains all the three pebbles. Clearly, we are done if  $v_0$  contains a pebble. Otherwise either  $v_1$  or  $v_2$  contains at least two pebbles. From this we can send one pebble to  $v_0$  and we are done.

**Case2:**  $C_3$  contains zero pebbles.  
**Case2:**  $C_3$  contains zero pebbles.

This implies that  $v_0$  contains all the three pebbles, and from this vertex we can send one pebble to  $v_0$  and we are done.  
 This implies that  $v_{p_1}$  contains all the three pebbles, and from this vertex we can send one pebble to  $v_0$  and we are done.

Thus, from Case1 and Case2,  $\psi(L(3,2)) \leq 3$ .  
 Thus, from Case1 and Case2,  $\psi(L(3,2)) \leq 3$ .

Therefore,  $\psi(L(3,2))=3$ .  
 Therefore,  $\psi(L(3,2))=3$ . ■

Here after we use the following notations: consider the paths  $P_A: v_0 v_1 v_2 \dots v_{k-2}$  and  $P_B: v_{k+1} v_{k+2} \dots v_{m-1} v_0$  belonging to the cycle  $C_m$ , where  $m = 2k-1$ . Let  $\hat{f}(v_i)$  be the number of pebbles at the vertex  $v_i$  and  $\hat{f}(P_A)$  be the number of pebbles on the path  $P_A$ .  
 Here after we use the following notations: consider the paths  $P_A: v_0 v_1 v_2 \dots v_{k-2}$  and  $P_B: v_{k+1} v_{k+2} \dots v_{m-1} v_0$  belonging to the cycle  $C_m$ , where  $m = 2k-1$ . Let  $\hat{f}(v_i)$  be the number of pebbles at the vertex  $v_i$  and  $\hat{f}(P_A)$  be the number of pebbles on the path  $P_A$ .

Consider the paths  $P_C: v_{p_1} v_{p_2} \dots v_{p_{n-1}}$  and  $P_D: v_{p_2} v_{p_3} \dots v_{p_{n-1}}$ .

**Theorem 2.3** Let  $L(3,n)$  be the lollipop graph, where  $n \geq 3$  then,

$$\psi(L(3,n)) = \begin{cases} 2\psi(P_n) + 1, & \text{if } \alpha_n = 0 \text{ or } 1 \\ 2\psi(P_n) - 1, & \text{if } \alpha_n = 2 \end{cases}$$

where  $n - 2 \equiv \alpha_n \pmod{3}$ .

**Proof:** Consider the lollipop graph  $L(3,n)$ , where  $n \geq 3$  and  $n - 2 \equiv \alpha_n \pmod{3}$ .

**Case1:** Let  $\alpha_n = 0$ . Then  $n \geq 5$ .

Consider the distribution of one pebble on  $v_1$  and  $2\psi(P_n) - 1$  pebbles on  $v_2$ . Clearly, we cannot cover dominate at least one of the vertices of  $L(3,n)$ . Thus,  $\psi(L(3,n)) \geq 2\psi(P_n) + 1$ .

Now, consider the distribution of  $2\psi(P_n) + 1$  pebbles on the vertices of  $L(3,n)$ .

**Case1.1:**  $C_3$  contains at least one pebble.

If  $P_C$  contains  $\psi(P_{n-1})$  or more pebbles then we are done, since  $\psi(C_3) = 1$ . So, assume that  $P_C$  contains  $x < \psi(P_{n-1})$  pebbles. This implies that  $C_3$  contains at least  $2\psi(P_n) + 1 - x$  pebbles. Suppose we cannot move  $\psi(P_n) - x$  pebbles to  $v_0$ , then we must have,

$$\hat{f}(v_0) + \left\lfloor \frac{\hat{f}(v_1)}{2} \right\rfloor + \left\lfloor \frac{\hat{f}(v_2)}{2} \right\rfloor \leq [\psi(P_n) - x] - 1.$$

$$\text{That is, } \hat{f}(v_0) + \frac{1}{2}(\hat{f}(v_1) + \hat{f}(v_2)) \leq \psi(P_n) - x. \quad \text{---- (1)}$$

To minimize the L.H.S of (1), it is sufficient to assume that  $\hat{f}(v_0) = 0$ . That is, we may assume that all the pebbles are placed at  $v_1$  and  $v_2$ .

From (1), we get  $\hat{f}(v_1) + \hat{f}(v_2) \leq 2[\psi(P_n) - x]$  ---- (2)

But, we have  $\hat{f}(v_1) + \hat{f}(v_2) \geq 2\psi(P_n) + 1 - x$  ---- (3)

The inequality in (2) contradicts the inequality in (3). So we can send  $\psi(P_n)-x$  pebbles to  $v_0$  and we cover dominate the path  $P_n$ (using at most  $2[\psi(P_n)-x]$  pebbles). Now  $C_3$  contains at least,  $2\psi(P_n)-x+1-[2(\psi(P_n)-x)]=x+1 \geq 1$  pebbles and we are done.

**Case1.2:**  $C_3$  contains zero pebbles.

This implies that  $P_C$  contains  $2\psi(P_n)+1$  pebbles. We use at most  $2^{n-1}$  pebbles to put a pebble at  $v_0$  so that we cover dominate  $C_3$ . Since  $v_{p_i}$  is also cover dominated by  $v_0$ , we need  $\psi(P_{n-2})$  pebbles in  $P_D$ . But we have enough pebbles in  $P_D$ , since  $\alpha_n=0$  and

$$2\psi(P_n)+1-2^{n-1} = 2\left(\frac{2^{n+1}-1}{7}\right) + 1 - 2^{n-1} = \frac{2^{n-1}+5}{7} \geq \psi(P_{n-2}), \text{ and we are done.}$$

**Case2:** Let  $\alpha_n=1$ . Then  $n \geq 3$ .

Consider the distribution of  $2\psi(P_n)$  pebbles on  $v_{p_{n-1}}$ . Clearly, we cannot cover dominate at least one of the vertices of  $L(3,n)$ . Thus,  $\psi(L(3,n)) \geq 2\psi(P_n)+1$ .

Now, consider the distribution of  $2\psi(P_n)+1$  pebbles on the vertices of  $L(3,n)$ .

**Case2.1:**  $C_3$  contains at least one pebble.

If  $P_C$  contains  $\psi(P_{n-1})$  or more pebbles then we are done, since  $\psi(C_3)=1$ . So, assume that  $P_C$  contains  $x < \psi(P_{n-1})$  pebbles. This implies that  $C_3$  contains at least  $2\psi(P_n)+1-x$  pebbles. Suppose we cannot move  $\psi(P_n)-x$  pebbles to  $v_0$ , then we must have,

$$\hat{f}(v_0) + \left\lfloor \frac{\hat{f}(v_1)}{2} \right\rfloor + \left\lfloor \frac{\hat{f}(v_2)}{2} \right\rfloor \leq [\psi(P_n) - x] - 1.$$

$$\text{That is, } \hat{f}(v_0) + \frac{1}{2}(\hat{f}(v_1) + \hat{f}(v_2)) \leq \psi(P_n) - x. \quad \text{---- (4)}$$

To minimize the L.H.S of (4), it is sufficient to assume that  $\hat{f}(v_0) = 0$ . That is, we may assume that all the pebbles are at  $v_1$  and  $v_2$ .

$$\text{From (4), we get } \hat{f}(v_1) + \hat{f}(v_2) \leq 2[\psi(P_n) - x]. \quad \text{---- (5)}$$

$$\text{But, we have } \hat{f}(v_1) + \hat{f}(v_2) \geq 2\psi(P_n) + 1 - x. \quad \text{---- (6)}$$

The inequality in (5) contradicts the inequality in (6). So we can send  $\psi(P_n) - x$  pebbles to  $v_0$  and we cover dominate the path  $P_n$  (using at most  $2[\psi(P_n) - x]$  pebbles). Now  $C_3$  contains at least,  $2\psi(P_n) - x + 1 - [2(\psi(P_n) - x)] = x + 1 \geq 1$  pebbles and we are done.

**Case2.2:**  $C_3$  contains zero pebbles.

This implies that  $P_C$  contains  $2\psi(P_n) + 1$  pebbles. We use at most  $2^{n-1}$  pebbles to put a pebble at  $v_0$  so that we cover dominate  $C_3$ . Since  $v_{p_1}$  is also cover dominated by  $v_0$ , we need  $\psi(P_{n-2})$  pebbles in  $P_D$ . But we have enough pebbles, since  $\alpha_n = 1$  and

$$2\psi(P_n) + 1 - 2^{n-1} = 2 \left( \frac{2^{n+1} - 2}{7} \right) + 1 - 2^{n-1} \geq \frac{2^{n-1} + 3}{7} \geq \psi(P_{n-2}), \text{ and we are done.}$$

**Case3 :** Let  $\alpha_n = 2$ . Then  $n \geq 4$ .

Consider the distribution of  $2\psi(P_n) - 2$  pebbles on  $v_{p_{n-1}}$ . Clearly, we cannot cover dominate at least one of the vertices of  $L(3, n)$ . Thus,

$$\psi(L(3, n)) \geq 2\psi(P_n) - 1.$$

Now, consider the distribution of  $2\psi(P_n) - 1$  pebbles on the vertices of  $L(3, n)$ .

**Case3.1 :**  $C_3$  contains at least one pebble.

If  $P_C$  contains  $\psi(P_{n-1})$  or more pebbles then we are done, since  $\psi(C_3)=1$ . So, assume that  $P_C$  contains  $x < \psi(P_{n-1})$  pebbles. This implies that  $C_3$  contains at least  $2\psi(P_n)-1-x$  pebbles. Suppose we cannot move  $\psi(P_n)-x$  pebbles to  $v_0$ , then we must have,

$$\hat{f}(v_0) + \left\lfloor \frac{\hat{f}(v_1)}{2} \right\rfloor + \left\lfloor \frac{\hat{f}(v_2)}{2} \right\rfloor \leq [\psi(P_n) - x] - 1.$$

That is,  $\hat{f}(v_0) + \frac{1}{2}(\hat{f}(v_1) + \hat{f}(v_2)) \leq \psi(P_n) - x.$  ----- (7)

To minimize the L.H.S of (7), it is sufficient to assume that  $\hat{f}(v_0) = 0$ . That is, we may assume that all the pebbles are at  $v_1$  and  $v_2$ .

From (7), we get  $\hat{f}(v_1) + \hat{f}(v_2) \leq 2[\psi(P_n) - x].$  ----- (8)

But, we have  $\hat{f}(v_1) + \hat{f}(v_2) \geq 2\psi(P_n) - 1 - x.$  ----- (9)

The inequality in (8) contradicts the inequality in (9). So we can send  $\psi(P_n)-x$  pebbles to  $v_0$  and we cover dominate the path  $P_n$ (using at most  $2[\psi(P_n)-x]$  pebbles). Now  $C_3$  contains at least,  $2\psi(P_n)-x-1-[2(\psi(P_n)-x)]=x-1 \geq 1$  ( $x \geq 2$ ) pebbles and we are done.

**Case3.2:**  $C_3$  contains zero pebbles.

This implies that  $P_C$  contains  $2\psi(P_n)-1$  pebbles. We use at most  $2^{n-1}$  pebbles to put a pebble at  $v_0$  so that we cover dominate  $C_3$ . Now we need  $\psi(P_{n-2})$  pebbles in  $P_D$ . But we have enough pebbles, since  $\alpha_n=2$  and  $2\psi(P_n)-1-2^{n-1} = 2\left(\frac{2^{n+1} + 3}{7}\right) - 1 - 2^{n-1} \geq \frac{2^{n-1} - 1}{7} \geq \psi(P_{n-2})$ , and we are done.

Thus, from Case1, Case2 and Case3 we get,

$$\psi(L(3, n)) \leq \begin{cases} 2\psi(P_n) + 1, & \text{if } \alpha_n = 0 \text{ or } 1 \\ 2\psi(P_n) - 1, & \text{if } \alpha_n = 2 \end{cases}$$

$$\text{Therefore, } \psi(L(3, n)) = \begin{cases} 2\psi(P_n) + 1, & \text{if } \alpha_n = 0 \text{ or } 1 \\ 2\psi(P_n) - 1, & \text{if } \alpha_n = 2 \end{cases} \quad \blacksquare$$

Next we proceed to find the domination cover pebbling number for  $L(m, 2)$ , where  $m=2k-1$  ( $k \geq 3$ ).

**Theorem 2.4** Let  $L(m, 2)$  be a lollipop graph where  $m=2k-1$  ( $k \geq 3$ ) and

$$k - 2 \equiv \alpha_k \pmod{3}. \text{ Then } \psi(L(m, 2)) = \begin{cases} 2\psi(C_m), & \text{if } \alpha_k = 0 \text{ or } 2 \\ 2\psi(C_m) + 1, & \text{if } \alpha_k = 1 \end{cases}.$$

**Proof:** Consider the lollipop graph  $L(m, 2)$ , where  $m=2k-1$  ( $k \geq 3$ ) and  $k - 2 \equiv \alpha_k \pmod{3}$ .

**Case 1:** Let  $\alpha_k=0$ . Then  $k \geq 5$ .

Consider the distribution of  $2\psi(C_m)-1$  pebbles on  $v_{p_1}$ , then clearly we cannot cover dominate at least one of the vertices of  $L(m, 2)$ . Thus,  $\psi(L(m, 2)) \geq 2\psi(C_m)$ .

Now, consider the distribution of  $2\psi(C_m)$  pebbles on the vertices of  $L(m, 2)$ , where  $\alpha_k=0$ .

**Case 1.1:**  $C_m$  contains at least  $\psi(C_m)$  pebbles.

If  $v_{p_1}$  contains one or more pebbles then we are done (by our assumption). So, assume that  $v_{p_1}$  contains zero pebbles. This implies that  $C_m$  contains  $2\psi(C_m)$  pebbles.

We have to send one pebble to  $v_0$ , to cover dominate the vertex  $v_{p_1}$ . Suppose we cannot send one pebble to  $v_0$ . Then we must have,

$$\hat{f}(P_A) + \left\lfloor \frac{\hat{f}(v_{k-1}) + \left\lfloor \frac{\hat{f}(v_k)}{2} \right\rfloor}{2} \right\rfloor \leq 2^{k-2} - 1$$

$$\text{and } \hat{f}(P_B) + \left\lfloor \frac{\hat{f}(v_k) + \left\lfloor \frac{\hat{f}(v_{k-1})}{2} \right\rfloor}{2} \right\rfloor \leq 2^{k-2} - 1.$$

Adding the above inequalities, we get

$$\hat{f}(P_A) + \hat{f}(P_B) + \left\lfloor \frac{\hat{f}(v_{k-1}) + \left\lfloor \frac{\hat{f}(v_k)}{2} \right\rfloor}{2} \right\rfloor + \left\lfloor \frac{\hat{f}(v_k) + \left\lfloor \frac{\hat{f}(v_{k-1})}{2} \right\rfloor}{2} \right\rfloor \leq 2^{k-1} - 2.$$

---- (10)

To minimize the L.H.S of (10), it is sufficient to assume that  $\hat{f}(P_A) = 0 = \hat{f}(P_B)$ .

That is, we may assume that all the pebbles are at  $v_{k-1}$  and  $v_k$ . Now,  $2\psi(C_m)$  is even, so

both  $\hat{f}(v_{k-1})$  and  $\hat{f}(v_k)$  are either odd or even.

**Subcase1 (a):** Suppose, both  $\hat{f}(v_{k-1})$  and  $\hat{f}(v_k)$  are odd.

$$\text{From (10), we get } \left\lfloor \frac{\hat{f}(v_{k-1}) + \left\lfloor \frac{\hat{f}(v_k)}{2} \right\rfloor}{2} \right\rfloor + \left\lfloor \frac{\hat{f}(v_k) + \left\lfloor \frac{\hat{f}(v_{k-1})}{2} \right\rfloor}{2} \right\rfloor \leq 2^{k-1} - 2.$$

$$\text{That is, } \frac{(\hat{f}(v_{k-1})-1) + \left(\frac{\hat{f}(v_k)-1}{2}\right)}{2} + \frac{(\hat{f}(v_k)-1) + \left(\frac{\hat{f}(v_{k-1})-1}{2}\right)}{2} \leq 2^{k-1} - 2.$$

$$\text{That is, } \frac{3}{4} \left[ \hat{f}(v_{k-1}) + \hat{f}(v_k) - 2 \right] \leq 2^{k-1} - 2. \quad \text{---- (11)}$$

$$\begin{aligned} \text{But, we have, } \hat{f}(v_{k-1}) + \hat{f}(v_k) &\geq 2\psi(C_m) \\ &= 2[2\psi(P_k) - |\alpha_k - 1|], \text{ since } m = 2k - 1 \\ &= 4\left(\frac{2^{k+1} - 1}{7}\right) - 2, \text{ since } \alpha_k = 0 \\ &= \frac{4(2^{k+1}) - 18}{7}. \end{aligned}$$

$$\text{That is, } \hat{f}(v_{k-1}) + \hat{f}(v_k) \geq \frac{8(2^k - 1) - 10}{7}.$$

Thus,

$$\begin{aligned} \frac{3}{4} \left( \hat{f}(v_{k-1}) + \hat{f}(v_k) - 2 \right) &\geq \frac{3}{4} \left( \frac{8(2^k - 1) - 10}{7} - 2 \right) = 6 \left( \frac{2^k - 4}{7} \right) \\ &\geq 2^{k-1}, \text{ since } k \geq 5. \quad \text{---- (12)} \end{aligned}$$

The inequality in (11) contradicts the inequality in (12).

**Subcase1 (b):** Suppose, both  $\hat{f}(v_{k-1})$  and  $\hat{f}(v_k)$  are even.

$$\text{From (10), we get } \left\lfloor \frac{\hat{f}(v_{k-1}) + \left\lfloor \frac{\hat{f}(v_k)}{2} \right\rfloor}{2} \right\rfloor + \left\lfloor \frac{\hat{f}(v_k) + \left\lfloor \frac{\hat{f}(v_{k-1})}{2} \right\rfloor}{2} \right\rfloor \leq 2^{k-1} - 2.$$

That is,  $\frac{3}{4}[\hat{f}(v_{k-1}) + \hat{f}(v_k)] \leq 2^{k-1} - 1$ . ---- (13)

But, we have,  $\hat{f}(v_{k-1}) + \hat{f}(v_k) \geq 2\psi(C_m)$  and since  $m=2k-1$  and  $\alpha_k=0$ , we get

$$\begin{aligned} \frac{3}{4}(\hat{f}(v_{k-1}) + \hat{f}(v_k)) &\geq \frac{3}{4}\left(\frac{8(2^k - 1) - 10}{7}\right) \\ &\geq 2^{k-1}, \text{ since } k \geq 5. \end{aligned} \quad \text{---- (14)}$$

The inequality in (13) contradicts the inequality in (14).

From the Subcase1 (a) and Subcase1 (b), we can send one pebble to  $v_0$  using at most  $2^{k-1}$  pebbles.

Now, the minimum number of pebbles that  $C_m$  contains is

$$\begin{aligned} 2\psi(C_m) - 2^{k-1} &= \psi(C_m) + \left[ 2\left(\frac{2^{k+1} - 1}{7}\right) - 1 \right] - 2^{k-1} \\ &= \psi(C_m) + \left(\frac{2^{k-1} - 9}{7}\right) \\ &\geq \psi(C_m), \end{aligned}$$

where the first equality follows since  $m=2k-1$  and  $\alpha_k=0$  and the third inequality follows since  $k \geq 5$ . Thus, we have enough pebbles to cover dominate  $C_m$  and we are done.

**Case1.2 :**  $C_m$  contains  $x < \psi(C_m)$  pebbles.

This implies that,  $v_{p_1}$  contains at least  $2\psi(C_m) - x$  pebbles. We can send  $\psi(C_m) -$

$$\left\lfloor \frac{x}{2} \right\rfloor \text{ pebbles to } v_0. \text{ So, } C_m \text{ contains at least } x + \psi(C_m) - \left\lfloor \frac{x}{2} \right\rfloor \geq \psi(C_m) \text{ pebbles and we}$$

are done.

**Case2 :** Let  $\alpha_k=2$ . Then  $k \geq 4$ .

Consider the distribution of  $2\psi(C_m)-1$  pebbles on  $v_{p_1}$ , then clearly we cannot cover dominate at least one of the vertices of  $L(m,2)$ . Thus,  $\psi(L(m,2)) \geq 2\psi(C_m)$ .

Now, consider the distribution of  $2\psi(C_m)$  pebbles on the vertices of  $L(m,2)$ , where  $\alpha_k=2$ .

**Case2.1 :**  $C_m$  contains at least  $\psi(C_m)$  pebbles.

If  $v_{p_1}$  contains one or more pebbles then we are done (by our assumption). So, assume that  $v_{p_1}$  contains zero pebbles. This implies that  $C_m$  contains  $2\psi(C_m)$  pebbles.

We have to send one pebble to  $v_0$ , to cover dominate the vertex  $v_{p_1}$ . Suppose we cannot send one pebble to  $v_0$ . Then we must have,

$$\hat{f}(P_A) + \hat{f}(P_B) + \left\lfloor \frac{\hat{f}(v_{k-1}) + \left\lfloor \frac{\hat{f}(v_k)}{2} \right\rfloor}{2} \right\rfloor + \left\lfloor \frac{\hat{f}(v_k) + \left\lfloor \frac{\hat{f}(v_{k-1})}{2} \right\rfloor}{2} \right\rfloor \leq 2^{k-1} - 2. \quad \text{---- (15)}$$

To minimize the L.H.S of (15), it is sufficient to assume that  $\hat{f}(P_A)=0=\hat{f}(P_B)$ . That is, we may assume that all the pebbles are at  $v_{k-1}$  and  $v_k$ . Now,  $2\psi(C_m)$  is even, so both  $\hat{f}(v_{k-1})$  and  $\hat{f}(v_k)$  are either odd or even.

**Subcase2 (a) :** Suppose, both  $\hat{f}(v_{k-1})$  and  $\hat{f}(v_k)$  are odd.

$$\text{From (15), we get } \frac{3}{4} \left[ \hat{f}(v_{k-1}) + \hat{f}(v_k) - 2 \right] \leq 2^{k-1} - 2. \quad \text{---- (16)}$$

$$\text{But, we have } \hat{f}(v_{k-1}) + \hat{f}(v_k) \geq 2\psi(C_m) = \frac{4(2^{k+1}) - 2}{7}.$$

But, we have  $\hat{f}(v_{k-1}) + \hat{f}(v_k) \geq 2\psi(C_m) = \frac{4(2^{k+1}) - 2}{7}$ .

That is,  $\hat{f}(v_{k-1}) + \hat{f}(v_k) \geq 2\left(\frac{4(2^k) - 1}{7}\right)$ .

$$\begin{aligned} \text{Thus, } \frac{3}{4}\left(\hat{f}(v_{k-1}) + \hat{f}(v_k) - 2\right) &\geq \frac{3}{4}\left[2\left(\frac{4(2^k) - 1}{7}\right) - 2\right] \\ &\geq 2^{k-1}, \text{ since } k \geq 4. \end{aligned} \quad \text{---- (17)}$$

The inequality in (16) contradicts the inequality in (17).

**Subcase2 (b):** Suppose, both  $\hat{f}(v_{k-1})$  and  $\hat{f}(v_k)$  are even.

From (15), we get

$$\frac{3}{4}\left[\hat{f}(v_{k-1}) + \hat{f}(v_k)\right] \leq 2^{k-1} - 1. \quad \text{---- (18)}$$

But, we have,  $\hat{f}(v_{k-1}) + \hat{f}(v_k) \geq 2\psi(C_m)$  and since  $m=2k-1$  and  $\alpha_k=2$ , we get

$$\begin{aligned} \frac{3}{4}\left(\hat{f}(v_{k-1}) + \hat{f}(v_k)\right) &\geq \frac{3}{4}\left[2\left(\frac{4(2^k) - 1}{7}\right)\right] \\ &\geq 2^{k-1}, \text{ since } k \geq 4. \end{aligned} \quad \text{---- (19)}$$

The inequality in (18) contradicts the inequality in (19).

From the Subcase2 (a) and Subcase2 (b), we can send one pebble to  $v_0$  using at most  $2^{k-1}$  pebbles.

Now, the minimum number of pebbles that  $C_m$  contains is

$$2\psi(C_m) - 2^{k-1} = \psi(C_m) + \left[ 2 \left( \frac{2^{k+1} + 3}{7} \right) - 1 \right] - 2^{k-1}, \text{ since } m = 2k - 1 \text{ and } \alpha_k = 2$$

$$\geq \psi(C_m), \text{ since } k \geq 4.$$

Thus, we have enough pebbles to cover dominate  $C_m$  and we are done.

**Case2.2 :**  $C_m$  contains  $x < \psi(C_m)$  pebbles.

This implies that,  $v_{p_1}$  contains at least  $2\psi(C_m) - x$  pebbles. We can send  $\psi(C_m) -$

$\left\lfloor \frac{x}{2} \right\rfloor$  pebbles to  $v_0$ . So,  $C_m$  contains at least  $x + \psi(C_m) - \left\lfloor \frac{x}{2} \right\rfloor \geq \psi(C_m)$  pebbles and we are done.

**Case3:** Let  $\alpha_k = 1$ . Then  $k \geq 3$ .

Consider the distribution of  $2\psi(C_m)$  pebbles on  $v_{p_1}$ . Then clearly we cannot cover dominate at least one of the vertices of  $L(m, 2)$ .

Thus,  $\psi(L(m, 2)) \geq 2\psi(C_m) + 1$ .

Now, consider the distribution of  $2\psi(C_m) + 1$  pebbles on the vertices of  $L(m, 2)$ , where  $\alpha_k = 1$ .

**Case3.1:**  $C_m$  contains at least  $\psi(C_m)$  pebbles.

If  $v_{p_1}$  contains one or more pebbles then we are done (by our assumption). So,

assume that  $v_{p_1}$  contains zero pebbles. This implies that  $C_m$  contains  $2\psi(C_m) + 1$  pebbles. We have to send one pebble to  $v_0$ , to cover dominate the vertex  $v_{p_1}$ .

Suppose we cannot send one pebble to  $v_0$ . Then we must have,

$$\hat{f}(P_A) + \hat{f}(P_B) + \left\lfloor \frac{\hat{f}(v_{k-1}) + \left\lfloor \frac{\hat{f}(v_k)}{2} \right\rfloor}{2} \right\rfloor + \left\lfloor \frac{\hat{f}(v_k) + \left\lfloor \frac{\hat{f}(v_{k-1})}{2} \right\rfloor}{2} \right\rfloor \leq 2^{k-1} - 2. \quad \text{---- (20)}$$

To minimize the L.H.S of (20), it is sufficient to assume that  $\hat{f}(P_A)=0= \hat{f}(P_B)$ . That is, we may assume that all the pebbles are at  $v_{k-1}$  and  $v_k$ . Now,  $2\psi(C_m)+1$  is odd, so exactly one of  $\hat{f}(v_{k-1}), \hat{f}(v_k)$  is even. Without loss of generality assume  $\hat{f}(v_{k-1})$  is even.

From (20), we get

$$\frac{3}{4} [\hat{f}(v_{k-1}) + \hat{f}(v_k)] - \frac{5}{4} \leq 2^{k-1} - 2. \quad \text{---- (21)}$$

But, we have,  $\hat{f}(v_{k-1}) + \hat{f}(v_k) \geq 2\psi(C_m) + 1$ . Then,

$$\frac{3}{4} (\hat{f}(v_{k-1}) + \hat{f}(v_k)) - \frac{5}{4} \geq 2^{k-1} \quad \text{---- (22)}$$

The inequality in (21) contradicts the inequality in (22). So, we can send one pebble to  $v_0$  using at most  $2^{k-1}$  pebbles.

Now, the minimum number of pebbles that  $C_m$  contains is

$$2\psi(C_m)+1-2^{k-1} \geq \psi(C_m).$$

Thus, we have enough pebbles to cover dominate  $C_m$  and we are done.

**Case3.2:**  $C_m$  contains  $x < \psi(C_m)$  pebbles.

This implies that,  $v_{p_1}$  contains at least  $2\psi(C_m) - x$  pebbles. We can send  $\psi(C_m) - \left\lfloor \frac{x}{2} \right\rfloor$  pebbles to  $v_0$ . So,  $C_m$  contains at least  $x + \psi(C_m) - \left\lfloor \frac{x}{2} \right\rfloor \geq \psi(C_m)$  pebbles and we are done.

$$\text{Thus, } \psi(L(m, 2)) \leq \begin{cases} 2\psi(C_m), & \text{if } \alpha_k = 0 \text{ or } 2 \\ 2\psi(C_m) + 1, & \text{if } \alpha_k = 1 \end{cases}.$$

$$\text{Therefore, } \psi(L(m, 2)) = \begin{cases} 2\psi(C_m), & \text{if } \alpha_k = 0 \text{ or } 2 \\ 2\psi(C_m) + 1, & \text{if } \alpha_k = 1 \end{cases}.$$

where  $m=2k-1$  ( $k \geq 3$ ) and  $k-2 \equiv \alpha_k \pmod{3}$ . ■

Next, we proceed to find the domination cover pebbling number of  $L(m, n)$ , where  $m=2k-1$  ( $k \geq 3$ ) and  $n \geq 3$ .

**Theorem 2.5** Let  $L(m, n)$  be a lollipop graph where  $m=2k-1$  ( $k \geq 3$ ) and  $n \geq 3$ . Then,

$$\psi(L(m, n)) = \begin{cases} 2^{n-1}\psi(C_m) + \psi(P_{n-1}), & \text{if } \alpha_k = 1 \\ 2^{n-1}\psi(C_m) + \psi(P_{n-2}), & \text{if } \alpha_k = 0 \text{ or } 2 \end{cases}$$

where  $k-2 \equiv \alpha_k \pmod{3}$ .

**Proof:** Consider the lollipop graph  $L(m, n)$ , where  $m=2k-1$  ( $k \geq 3$ ) and  $n \geq 3$ .

**Case 1:** Let  $\alpha_k = 1$ . Then  $k \geq 3$ .

Consider the distribution of  $\psi(L(m, n)) - 1$  pebbles at  $v_{p_{n-1}}$ . Clearly, we cannot cover dominate at least one of the vertices of  $L(m, n)$ .

Thus,  $\psi(L(m, n)) \geq 2^{n-1}\psi(C_m) + \psi(P_{n-1})$ .

Now, consider the distribution of  $\psi(L(m,n))$  pebbles on the vertices of  $L(m,n)$ .

**Case1.1:**  $C_m$  contains at least  $\psi(C_m)$  pebbles.

If  $P_C$  contains  $\psi(P_{n-1})$  pebbles are more, then clearly we are done (by our assumption). So assume that  $P_C$  contains  $x < \psi(P_{n-1})$  pebbles. This implies that,  $C_m$  contains  $2^{n-1}\psi(C_m) + \psi(P_{n-1}) - x$  pebbles. Suppose, we cannot move  $\psi(P_n) - x$  pebbles to  $v_0$ , then we must have,

$$\hat{f}(P_A) + \left\lfloor \frac{\hat{f}(v_{k-1}) + \left\lfloor \frac{\hat{f}(v_k)}{2} \right\rfloor}{2} \right\rfloor \leq 2^{k-2} [\psi(P_n) - x] - 1$$

$$\text{and } \hat{f}(P_B) + \left\lfloor \frac{\hat{f}(v_k) + \left\lfloor \frac{\hat{f}(v_{k-1})}{2} \right\rfloor}{2} \right\rfloor \leq 2^{k-2} [\psi(P_n) - x] - 1.$$

Adding the above inequalities, we get

$$\begin{aligned} & \hat{f}(P_A) + \hat{f}(P_B) + \left\lfloor \frac{\hat{f}(v_{k-1}) + \left\lfloor \frac{\hat{f}(v_k)}{2} \right\rfloor}{2} \right\rfloor \\ & + \left\lfloor \frac{\hat{f}(v_k) + \left\lfloor \frac{\hat{f}(v_{k-1})}{2} \right\rfloor}{2} \right\rfloor \leq 2^{k-1} [\psi(P_n) - x] - 2. \quad \text{---- (23)} \end{aligned}$$

To minimize the L.H.S of (23), it is sufficient to assume that  $\hat{f}(P_A)=0= \hat{f}(P_B)$ .

That is, we may assume that all the pebbles are at  $v_k$  and  $v_{k-1}$ .

Now,  $2^{n-1}\psi(C_m)+\psi(P_{n-1})-x$  is odd or even, since it depends on both

$\psi(P_{n-1})$  and  $x$ .

**Subcase1 (a):** Suppose,  $\hat{f}(v_{k-1}) + \hat{f}(v_k)$  is even.

This implies that, both  $\hat{f}(v_{k-1})$  and  $\hat{f}(v_k)$  are odd or even. Suppose, both

$\hat{f}(v_{k-1})$  and  $\hat{f}(v_k)$  are odd, then from (23), we get

$$\left\lfloor \frac{\hat{f}(v_{k-1}) + \left\lfloor \frac{\hat{f}(v_k)}{2} \right\rfloor}{2} \right\rfloor + \left\lfloor \frac{\hat{f}(v_k) + \left\lfloor \frac{\hat{f}(v_{k-1})}{2} \right\rfloor}{2} \right\rfloor \leq 2^{k-1} [\psi(P_n) - x] - 2.$$

$$\text{That is, } \frac{3}{4} [\hat{f}(v_{k-1}) + \hat{f}(v_k) - 2] \leq 2^{k-1} [\psi(P_n) - x] - 2. \quad \text{---- (24)}$$

But, we have  $\hat{f}(v_k) + \hat{f}(v_{k-1}) \geq 2^{n-1}\psi(C_m)+\psi(P_{n-1})-x$

$$= 2^{n-1} [2\psi(P_k) - |\alpha_k - 1|] + \psi(P_{n-1}) - x$$

$$\geq 2^n \left[ \frac{2^{k+1} - 2}{7} \right] + \frac{2^n - 2}{7} - x, \text{ where the second equality follows since } m=2k-1,$$

and the third inequality follows since  $\alpha_k = 1$  and  $\psi(P_n) \geq \frac{2^{n+1} - 2}{7}$ .

$$\text{Then } \frac{3}{4} [\hat{f}(v_k) + \hat{f}(v_{k-1}) - 2] \geq \frac{3}{4} \left[ 2^n \left[ \frac{2^{k+1} - 2}{7} \right] + \frac{2^n - 2}{7} \right] - \frac{3}{4}x - \frac{3}{2}$$

$$\begin{aligned}
 &= \frac{3}{4} \left[ \frac{2^k(2^{n+1} + 3)}{7} - \frac{3(2^k)}{7} - \frac{2^n}{7} \right] - \frac{3}{4}x - \frac{24}{14} \\
 &\geq 3(2^{k-2})\psi(P_n) - \frac{3}{4} \left[ \frac{3(2^k)}{7} + \frac{2^n}{7} \right] - \frac{3}{4}x - \frac{24}{14} \\
 &\geq 2^{k-1}\psi(P_n) + 2^{k-2} \left[ \frac{2^{n+1} - 2}{7} - \frac{9(2^k)}{28(2^{k-2})} - \frac{3(2^n)}{28(2^{k-2})} \right] - \frac{3}{4}x - \frac{12}{7} \\
 &\geq 2^{k-1}\psi(P_n) + 2^{k-2} \left[ \frac{2^{n+1} - 2}{7} - \frac{36}{28(2)} - \frac{3(2^n)}{28(2)} \right] - \frac{3}{4}x - \frac{12}{7} \\
 &= 2^{k-1}\psi(P_n) + 2^{k-2} \left[ \frac{13(2^n) - 52}{56} \right] - x - 2,
 \end{aligned}$$

where the third inequality follows since  $\psi(P_n) \leq \frac{2^{n+1} + 3}{7}$ .

$$\text{That is, } \frac{3}{4} \left[ \hat{f}(v_k) + \hat{f}(v_{k-1}) - 2 \right] \geq 2^{k-1}\psi(P_n) - x - 2. \quad \text{---- (25)}$$

The inequality in (24) contradicts the inequality in (25).

Suppose, both  $\hat{f}(v_{k-1})$  and  $\hat{f}(v_k)$  are even, then from (23), we get

$$\frac{(\hat{f}(v_{k-1}) - 1) + \left( \frac{\hat{f}(v_k)}{2} \right)}{2} + \frac{(\hat{f}(v_k) - 1) + \left( \frac{\hat{f}(v_{k-1})}{2} \right)}{2} \leq 2^{k-1}[\psi(P_n) - x] - 2.$$

$$\text{That is, } \frac{3}{4} \left[ \hat{f}(v_{k-1}) + \hat{f}(v_k) \right] \leq 2^{k-1}[\psi(P_n) - x] - 1. \quad \text{---- (26)}$$

$$\begin{aligned}
\text{But, we have } \hat{f}(v_k) + \hat{f}(v_{k-1}) &\geq 2^{n-1}\psi(C_m) + \psi(P_{n-1}) - x \\
&= 2^{n-1} [2\psi(P_k) - |\alpha_k - 1|] + \psi(P_{n-1}) - x \\
&\geq 2^n \left[ \frac{2^{k+1} - 2}{7} \right] + \frac{2^n - 2}{7} - x, \text{ where the second equality follows since } m=2k-1,
\end{aligned}$$

and the third inequality follows since  $\alpha_k = 1$  and  $\psi(P_n) \geq \frac{2^{n+1} - 2}{7}$ .

$$\begin{aligned}
\text{That is, } \frac{3}{4} [\hat{f}(v_k) + \hat{f}(v_{k-1})] &\geq \frac{3}{4} \left[ 2^n \left[ \frac{2^{k+1} - 2}{7} \right] + \frac{2^n - 2}{7} \right] - \frac{3}{4}x \\
&\geq 2^{k-1}\psi(P_n) + 2^{k-2} \left[ \frac{13(2^n) - 52}{56} \right] - x - 2.
\end{aligned}$$

$$\text{That is, } \frac{3}{4} [\hat{f}(v_k) + \hat{f}(v_{k-1})] \geq 2^{k-1}\psi(P_n) - x - 1. \quad \text{---- (27)}$$

The inequality in (26) contradicts the inequality in (27).

**Subcase1(b):** If  $\hat{f}(v_{k-1}) + \hat{f}(v_k)$  is odd.

Without loss of generality, let  $\hat{f}(v_k)$  be odd. Then  $\hat{f}(v_{k-1})$  is even.

From (23), we get

$$\frac{(\hat{f}(v_{k-1}) - 1) + \left( \frac{\hat{f}(v_k) - 1}{2} \right)}{2} + \frac{(\hat{f}(v_k) - 1) + \left( \frac{\hat{f}(v_{k-1})}{2} \right)}{2} \leq 2^{k-1} [\psi(P_n) - x] - 2.$$

$$\text{That is, } \frac{3}{4} [\hat{f}(v_{k-1}) + \hat{f}(v_k)] - \frac{5}{4} \leq 2^{k-1} [\psi(P_n) - x] - 2. \quad \text{---- (28)}$$

But, we have  $\hat{f}(v_k) + \hat{f}(v_{k-1}) \geq 2^{n-1}\psi(C_m) + \psi(P_{n-1}) - x$

$$= 2^{n-1} [2\psi(P_k) - |\alpha_k - 1|] + \psi(P_{n-1}) - x$$

$$\geq 2^n \left[ \frac{2^{k+1} - 2}{7} \right] + \frac{2^n - 2}{7} - x, \text{ where the second equality follows since } m=2k-1,$$

and the third inequality follows since  $\alpha_k = 1$  and  $\psi(P_n) \geq \frac{2^{n+1} - 2}{7}$ .

That is,  $\frac{3}{4} [\hat{f}(v_k) + \hat{f}(v_{k-1})] - \frac{5}{4} \geq \frac{3}{4} \left[ 2^n \left( \frac{2^{k+1} - 2}{7} \right) + \frac{2^n - 2}{7} \right] - \frac{3}{4}x - \frac{5}{4}$

$$\geq 2^{k-1}\psi(P_n) + 2^{k-2} \left[ \frac{13(2^n) - 52}{56} \right] - x - 2.$$

That is,  $\frac{3}{4} [\hat{f}(v_k) + \hat{f}(v_{k-1})] - \frac{5}{4} \geq 2^{k-1}\psi(P_n) - x - 2. \dots (29)$

The inequality in (28) contradicts the inequality in (29).

From Subcase 1(a) and Subcase 1(b), we can always send  $\psi(P_n) - x$  pebbles to  $v_0$  at a cost of at most  $2^{k-1}[\psi(P_n) - x]$  pebbles. Thus, we cover dominate the path  $P_n$ . Now, we have to cover dominate  $C_m$ . In  $C_m$ , we have at least  $2^{n-1}\psi(C_m) + \psi(P_{n-1}) - x - 2^{k-1}[\psi(P_n) - x]$  pebbles. We need at most  $\psi(C_m)$  pebbles to cover dominate  $C_m$ . But,

$$2^{n-1}\psi(C_m) + \psi(P_{n-1}) - x - 2^{k-1}[\psi(P_n) - x] - \psi(C_m)$$

$$= (2^{n-1} - 1)\psi(C_m) + \psi(P_{n-1}) - x - 2^{k-1}[\psi(P_n) - x]$$

$$= (2^{n-1} - 1)[2\psi(P_k)] - 2^{k-1}\psi(P_n) + \psi(P_{n-1}) + (2^{k-1} - 1)x$$

$$\begin{aligned}
&\geq (2^{n-1} - 1) \left( \frac{2(2^{k+1} - 2)}{7} \right) - 2^{k-1} \left( \frac{2^{n+1} + 3}{7} \right) \\
&= 2^{k-1} \left[ \frac{4(2^n) - 8 - 2(2^n) - 3}{7} - \frac{4(2^n) - 4}{7(2^{k-1})} \right] \\
&\geq 2^{k-1} \left[ \frac{8(2^n) - 4(2^n) - 15}{28} \right] \\
&\geq 2^{k-1} \left[ \frac{4(2^n) - 15}{28} \right] > 0,
\end{aligned}$$

where the second equality follows since  $m=2k-1$ , the third inequality follows since

$\alpha_k = 1$  and  $\psi(P_n) \leq \frac{2^{n+1} + 3}{7}$ , the fifth inequality follows since  $k \geq 3$ , and the sixth inequality follows *since  $n > 2$  and  $k > 2$ .*

Thus, we have enough pebbles to cover dominate  $C_m$  and hence we are done.

**Case1.2:**  $C_m$  contains  $y < \psi(C_m)$  pebbles.

This implies that,  $P_C$  contains  $2^{n-1}\psi(C_m) + \psi(P_{n-1}) - y$  pebbles. We use at most  $\psi(P_{n-1})$  pebbles to cover dominate  $P_C$ . Thus, we have at least  $2^{n-1}\psi(C_m) - y$  pebbles in  $P_C$ . We need at most  $2^{n-1}[\psi(C_m) - y]$  pebbles from  $P_C$  to cover the vertices of  $C_m$ . But,

$$\begin{aligned}
&2^{n-1}\psi(C_m) - y - 2^{n-1}[\psi(C_m) - y] \\
&= (2^{n-1} - 1)y > 0,
\end{aligned}$$

where the second inequality follows since  $n > 2$ . Thus, we can send  $\psi(C_m)$ -y pebbles to  $v_0$  and already  $C_m$  contains y pebbles implies that  $C_m$  contains  $\psi(C_m)$  pebbles and we are done.

So,  $\psi(L(m, n)) \leq 2^{n-1}\psi(C_m) + \psi(P_{n-1})$ .

Therefore,  $\psi(L(m, n)) = 2^{n-1}\psi(C_m) + \psi(P_{n-1})$ , if  $\alpha_k = 1$ .

**Case2:** Let  $\alpha_k = 2$ . Then  $k \geq 4$ .

Consider the distribution of  $\psi(L(m, n))$ -1 pebbles at  $v_{p_{n-1}}$ . Clearly, we cannot cover dominate at least one of the vertices of  $L(m, n)$ .

Thus,  $\psi(L(m, n)) \geq 2^{n-1}\psi(C_m) + \psi(P_{n-2})$ .

Now, consider the distribution of  $\psi(L(m, n))$  pebbles on the vertices of  $L(m, n)$ .

**Case2.1:**  $C_m$  contains at least  $\psi(C_m)$  pebbles.

If  $P_C$  contains  $\psi(P_{n-1})$  pebbles are more, then clearly we are done (by our assumption). So assume that  $P_C$  contains  $x < \psi(P_{n-1})$  pebbles. This implies that,  $C_m$  contains  $2^{n-1}\psi(C_m) + \psi(P_{n-2}) - x$  pebbles. Suppose, we cannot move  $\psi(P_n) - x$  pebbles to  $v_0$ , then we must have,

$$\hat{f}(P_A) + \hat{f}(P_B) + \left\lfloor \frac{\hat{f}(v_{k-1}) + \left\lfloor \frac{\hat{f}(v_k)}{2} \right\rfloor}{2} \right\rfloor + \left\lfloor \frac{\hat{f}(v_k) + \left\lfloor \frac{\hat{f}(v_{k-1})}{2} \right\rfloor}{2} \right\rfloor \leq 2^{k-1}[\psi(P_n) - x] - 2. \quad \text{---- (30)}$$

To minimize the L.H.S of (30), it is sufficient to assume that  $\hat{f}(P_A)=0=\hat{f}(P_B)$ .

That is, we may assume that all the pebbles are at  $v_k$  and  $v_{k-1}$ .

Now,  $2^{n-1}\psi(C_m)+\psi(P_{n-2})-x$  is odd or even, since it depends on both

$\psi(P_{n-2})$  and  $x$ .

**Subcase2 (a):** Suppose,  $\hat{f}(v_{k-1})+\hat{f}(v_k)$  is even.

This implies that, both  $\hat{f}(v_{k-1})$  and  $\hat{f}(v_k)$  are odd or even. Suppose, both

$\hat{f}(v_{k-1})$  and  $\hat{f}(v_k)$  are odd, then

From (30), we get

$$\frac{3}{4}[\hat{f}(v_{k-1})+\hat{f}(v_k)-2] \leq 2^{k-1}[\psi(P_n)-x]-2. \text{ ---- (31)}$$

But, we have  $\hat{f}(v_k)+\hat{f}(v_{k-1}) \geq 2^{n-1}\psi(C_m)+\psi(P_{n-2})-x$

$$= 2^{n-1}[2\psi(P_k)-|\alpha_k-1|]+\psi(P_{n-2})-x$$

$$\geq 2^n \left[ \frac{2^{k+1}+3}{7} - \frac{1}{2} \right] + \frac{2^{n-1}-2}{7} - x,$$

where the second equality follows since  $m=2k-1$ , and the third inequality follows

since  $\alpha_k = 2$  and  $\psi(P_n) \geq \frac{2^{n+1}-2}{7}$ .

$$\text{That is, } \frac{3}{4}[\hat{f}(v_k)+\hat{f}(v_{k-1})-2] \geq \frac{3}{4} \left[ 2^n \left[ \frac{2^{k+1}+3}{7} - \frac{1}{2} \right] + \frac{2^{n-1}-2}{7} \right] - \frac{3}{4}x - \frac{3}{2}$$

$$\geq 2^{k-1}\psi(P_n)+2^{k-2}\psi(P_n)-\frac{3}{4} \left[ \frac{3(2^k)}{7} \right] - \frac{3}{4}x - 2$$

$$\geq 2^{k-1}\psi(P_n) + 2^{k-2} \left[ \frac{2^{n+1} - 2}{7} - \frac{3}{4} \left( \frac{12}{7} \right) \right] - \frac{3}{4}x - 2$$

$$\geq 2^{k-1}\psi(P_n) - x - 2,$$

where the second inequality follows *since*  $\psi(P_n) \leq \frac{2^{n+1} + 3}{7}$ , and the fourth inequality follows *since*  $n \geq 3$  and  $k \geq 4$ .

$$\text{That is, } \frac{3}{4} [\hat{f}(v_k) + \hat{f}(v_{k-1}) - 2] \geq 2^{k-1}\psi(P_n) - x - 2. \quad \text{---- (32)}$$

The inequality in (31) contradicts the inequality in (32).

Suppose, both  $\hat{f}(v_{k-1})$  and  $\hat{f}(v_k)$  are even, then

From (30), we get

$$\frac{3}{4} [\hat{f}(v_{k-1}) + \hat{f}(v_k)] \leq 2^{k-1} [\psi(P_n) - x] - 1. \quad \text{---- (33)}$$

But, we have  $\hat{f}(v_k) + \hat{f}(v_{k-1}) \geq 2^{n-1}\psi(C_m) + \psi(P_{n-2}) - x$

$$\geq 2^n \left[ \frac{2^{k+1} + 3}{7} - \frac{1}{2} \right] + \frac{2^{n-1} - 2}{7} - x,$$

where the second inequality follows since  $\alpha_k = 2$  and  $\psi(P_n) \geq \frac{2^{n+1} - 2}{7}$ .

$$\text{That is, } \frac{3}{4} [\hat{f}(v_k) + \hat{f}(v_{k-1})] \geq \frac{3}{4} \left[ 2^n \left[ \frac{2^{k+1} + 3}{7} - \frac{1}{2} \right] + \frac{2^{n-1} - 2}{7} \right] - \frac{3}{4}x$$

$$\begin{aligned}
&\geq 2^{k-1}\psi(P_n) + 2^{k-2}\psi(P_n) - \frac{3}{4}\left[\frac{3(2^k)}{7}\right] - x - 1 \\
&\geq 2^{k-1}\psi(P_n) + 2^{k-2}\left[\frac{2^{n+1}-2}{7} - \frac{3}{4}\left(\frac{12}{7}\right)\right] - x - 1 \\
&\geq 2^{k-1}\psi(P_n) - x - 1,
\end{aligned}$$

where the second inequality follows since  $\psi(P_n) \leq \frac{2^{n+1}+3}{7}$ , and the fourth inequality follows *since*  $n \geq 3$  and  $k \geq 4$ .

$$\text{That is, } \frac{3}{4}\left[\hat{f}(v_k) + \hat{f}(v_{k-1})\right] \geq 2^{k-1}\psi(P_n) - x - 1. \quad \text{---- (34)}$$

The inequality in (33) contradicts the inequality in (34).

**Subcase2 (b):** If  $\hat{f}(v_{k-1}) + \hat{f}(v_k)$  is odd.

Without loss of generality, let  $\hat{f}(v_k)$  be odd. Then  $\hat{f}(v_{k-1})$  is even.

From (30), we get

$$\frac{3}{4}\left[\hat{f}(v_{k-1}) + \hat{f}(v_k)\right] - \frac{5}{4} \leq 2^{k-1}[\psi(P_n) - x] - 2. \quad \text{---- (35)}$$

But, we have  $\hat{f}(v_k) + \hat{f}(v_{k-1}) \geq 2^{n-1}\psi(C_m) + \psi(P_{n-2}) - x$

$$\geq 2^n \left[ \frac{2^{k+1}+3}{7} - \frac{1}{2} \right] + \frac{2^{n-1}-2}{7} - x,$$

where the second equality follows since  $m=2k-1$ , and the third inequality follows

since  $\alpha_k = 2$  and  $\psi(P_n) \geq \frac{2^{n+1} - 2}{7}$ .

$$\begin{aligned} \text{That is, } & \frac{3}{4} \left[ \hat{f}(v_k) + \hat{f}(v_{k-1}) \right] - \frac{5}{4} \geq \frac{3}{4} \left[ 2^n \left( \frac{2^{k+1} + 3}{7} - \frac{1}{2} \right) + \frac{2^{n-1} - 2}{7} \right] - \frac{3}{4}x - \frac{5}{4} \\ & = 2^{k-1} \psi(P_n) + 2^{k-2} \left[ \frac{2^{n+1} - 11}{7} \right] - x - 2. \end{aligned}$$

$$\text{That is, } \frac{3}{4} \left[ \hat{f}(v_k) + \hat{f}(v_{k-1}) \right] - \frac{5}{4} \geq 2^{k-1} \psi(P_n) - x - 2. \quad \text{---- (36)}$$

The inequality in (35) contradicts the inequality in (36).

From Subcase2 (a) and Subcase2 (b), we can always send  $\psi(P_n) - x$  pebbles to  $v_0$  at a cost of at most  $2^{k-1}[\psi(P_n) - x]$  pebbles. Thus, we cover dominate the path  $P_n$ . Now, we have to cover dominate  $C_m$ . In  $C_m$ , we have at least  $2^{n-1} \psi(C_m) + \psi(P_{n-2}) - x - 2^{k-1}[\psi(P_n) - x]$  pebbles. We need at most  $\psi(C_m)$  pebbles to cover dominate  $C_m$ . But,

$$\begin{aligned} & 2^{n-1} \psi(C_m) + \psi(P_{n-2}) - x - 2^{k-1}[\psi(P_n) - x] - \psi(C_m) \\ & = (2^{n-1} - 1)[2\psi(P_k) - 1] - 2^{k-1} \psi(P_n) + \psi(P_{n-2}) + (2^{k-1} - 1)x \\ & \geq (2^{n-1} - 1) \left( \frac{2(2^{k+1} + 3)}{7} - 1 \right) - 2^{k-1} \left( \frac{2^{n+1} + 3}{7} \right) \\ & = 2^{k-1} \left[ \frac{4(2^n) - 8 - 2(2^n) - 3}{7} - \frac{2^{n-1} - 1}{7(2^{k-1})} \right] \\ & \geq 2^{k-1} \left[ \frac{31(2^{n-1}) - 87}{56} \right] > 0, \end{aligned}$$

where the second equality follows since  $\alpha_k = 1$  and  $\psi(P_n) \leq \frac{2^{n+1} + 3}{7}$ , and the fourth inequality follows since  $n > 2$  and  $k > 3$ .

Thus, we have enough pebbles to cover dominate  $C_m$  and hence we are done.

**Case2.2:**  $C_m$  contains  $y < \psi(C_m)$  pebbles.

This implies that,  $P_C$  contains  $2^{n-1}\psi(C_m) + \psi(P_{n-2}) - y$  pebbles. We use at most  $\psi(P_{n-1})$  pebbles to cover dominate  $P_C$ . Thus, we have at least  $2^{n-1}\psi(C_m) + \psi(P_{n-2}) - y - \psi(P_{n-1})$  pebbles in  $P_C$ . We need at most  $2^{n-1}[\psi(C_m) - y]$  pebbles from  $P_C$  to cover dominate the vertices of  $C_m$ . But,

$$\begin{aligned} & 2^{n-1}\psi(C_m) + \psi(P_{n-2}) - y - \psi(P_{n-1}) - 2^{n-1}[\psi(C_m) - y] \\ & \geq 2^{n-1}y + \frac{2^{n-1} - 2}{7} - y - \frac{2^n + 3}{7} \\ & \geq 2^{n-1} \left[ y - \frac{5 + 7y}{7(4)} - \frac{1}{7} \right] \\ & = 2^{n-1} \left[ \frac{21y - 9}{28} \right] > 0 \text{ if } y > 0, \end{aligned}$$

where the second inequality follows since  $n \geq 3$ . Thus, we can send  $\psi(C_m) - y$  pebbles to  $v_0$  and already  $C_m$  contains  $y$  pebbles implies that  $C_m$  contains  $\psi(C_m)$  pebbles and we are done.

So,  $\psi(L(m, n)) \leq 2^{n-1}\psi(C_m) + \psi(P_{n-2})$ .

Therefore,  $\psi(L(m, n)) = 2^{n-1}\psi(C_m) + \psi(P_{n-2})$ , if  $\alpha_k = 2$ .

**Case3:** Let  $\alpha_k = 0$ . Then  $k \geq 5$ .

Consider the distribution of  $\psi(L(m,n))$ -1 pebbles at  $v_{p_{n-1}}$ . Clearly, we cannot cover dominate at least one of the vertices of  $L(m,n)$ .

Thus,  $\psi(L(m,n)) \geq 2^{n-1}\psi(C_m) + \psi(P_{n-2})$ .

Now, consider the distribution of  $\psi(L(m,n))$  pebbles on the vertices of  $L(m,n)$ .

**Case3.1** :  $C_m$  contains at least  $\psi(C_m)$  pebbles.

If  $P_C$  contains  $\psi(P_{n-1})$  pebbles are more, then clearly we are done (by our assumption). So assume that  $P_C$  contains  $x < \psi(P_{n-1})$  pebbles. This implies that,  $C_m$  contains  $2^{n-1}\psi(C_m) + \psi(P_{n-2}) - x$  pebbles. Suppose, we cannot move  $\psi(P_n) - x$  pebbles to  $v_0$ , then we must have,

$$\hat{f}(P_A) + \hat{f}(P_B) + \left\lfloor \frac{\hat{f}(v_{k-1}) + \left\lfloor \frac{\hat{f}(v_k)}{2} \right\rfloor}{2} \right\rfloor + \left\lfloor \frac{\hat{f}(v_k) + \left\lfloor \frac{\hat{f}(v_{k-1})}{2} \right\rfloor}{2} \right\rfloor \leq 2^{k-1}[\psi(P_n) - x] - 2. \quad \text{---- (37)}$$

To minimize the L.H.S of (37), it is sufficient to assume that  $\hat{f}(P_A) = 0 = \hat{f}(P_B)$ .

That is, we may assume that all the pebbles are at  $v_k$  and  $v_{k-1}$ .

Now,  $2^{n-1}\psi(C_m) + \psi(P_{n-2}) - x$  is odd or even, since it depends on both  $\psi(P_{n-2})$  and  $x$ .

$\hat{f}(v_{k-1}) + \hat{f}(v_k)$  is even. **Subcase (a) :** Suppose,  $\hat{f}(v_{k-1}) + \hat{f}(v_k)$  is even.  
 $f(v_{k-1}) + f(v_k)$  is even.

both  $\hat{f}(v_{k-1})$  and  $\hat{f}(v_k)$  are odd or even. This implies that, both  $\hat{f}(v_{k-1})$  and  $\hat{f}(v_k)$  are odd or even.  
 This implies that, both  $f(v_{k-1})$  and  $f(v_k)$  are odd or even.

$\hat{f}(v_{k-1})$  and  $\hat{f}(v_k)$  are odd, then from (37), we get  
 Suppose, both  $f(v_{k-1})$  and  $f(v_k)$  are odd, then from (37), we get  
 Suppose, both  $f(v_{k-1})$  and  $f(v_k)$  are odd, then from (37), we get

$$-2] \leq 2^{k-1} [\psi(P_n) - x] - 2. \quad \text{---- (38)}$$

$$\frac{3}{4} [\hat{f}(v_{k-1}) + \hat{f}(v_k) - 2] \leq 2^{k-1} [\psi(P_n) - x] - 2. \quad \text{---- (38)}$$

$$) + \hat{f}(v_{k-1}) \geq 2^{n-1} \psi(C_m) + \psi(P_{n-2}) - x$$

But, we have  $f(v_k) + f(v_{k-1}) \geq 2^{n-1} \psi(C_m) + \psi(P_{n-2}) - x$

$$\equiv 2^{n-1} [2\psi(P_k) - |\alpha_k - 1|] + \psi(P_{n-2}) - x$$

$$= \frac{2^{n-1} [2\psi(P_k) - |\alpha_k - 1|] + \psi(P_{n-2}) - x}{2^{n-1} [2\psi(P_k) - |\alpha_k - 1|] + \psi(P_{n-2}) - x}$$

$$-1] + \frac{2^{n-1} - 2}{7} - x \geq \frac{2^{n-1} - 2}{7} - x,$$

$$\geq \frac{2^{n-1} - 2}{7} - x,$$

equality follows since  $m=2k-1$ , and the third inequality follows  
 where the second equality follows since  $m=2k-1$ , and the third inequality follows

$$\psi(P_n) \geq \frac{2^{n+1} - 2}{7}.$$

since  $\alpha_k = 2$  and  $\psi(P_n) \geq \frac{2^{n+1} - 2}{7}$ .  
 since  $\alpha_k = 2$  and  $\psi(P_n) \geq \frac{2^{n+1} - 2}{7}$ .

$$+ \hat{f}(v_{k-1}) - 2] \geq \frac{3}{4} \left[ \frac{2^{k+1} - 1}{7} - \frac{1}{2} \right] + \frac{2^{n-1} - 2}{7} - x - \frac{3}{4} x - \frac{3}{2}$$

That is,  $\frac{3}{4} [f(v_{k-1}) + f(v_{k-1}) - 2] \geq \frac{3}{4} \left[ \frac{2^{k+1} - 1}{7} - \frac{1}{2} \right] + \frac{2^{n-1} - 2}{7} - \frac{3}{4} x - \frac{3}{2}$   
 That is,  $\frac{3}{4} [f(v_k) + f(v_{k-1}) - 2] \geq \frac{3}{4} \left[ \frac{2^{k+1} - 1}{7} - \frac{1}{2} \right] + \frac{2^{n-1} - 2}{7} - \frac{3}{4} x - \frac{3}{2}$

$$2\psi(P_n) - \frac{3}{4} \left[ \frac{3(2^k)}{7} - \frac{8(2^{n-1})}{7} \right] - \frac{3}{4} x - 2$$

$$\geq \frac{3}{4} \left[ \frac{3(2^k)}{7} - \frac{8(2^{n-1})}{7} \right] - \frac{3}{4} x - 2$$

$$2 \left[ \frac{2^{n+1} - 2}{7} - \frac{3}{4} \left( \frac{12}{7} \right) - \frac{8(2^{n-1})}{7} \right] + \frac{3}{4} \left[ \frac{2^{n+1} - 2}{7} - \frac{3}{4} \left( \frac{12}{7} \right) - \frac{8(2^{n-1})}{7} \right] - \frac{3}{4} x - 2$$

$$\geq \frac{2^{n+1} - 2}{7} - \frac{3}{4} \left( \frac{12}{7} \right) - \frac{8(2^{n-1})}{7} - \frac{3}{4} x - 2$$

$$2 \left[ \frac{8(2^{n+1} - 11) - 8(2^{n-1})}{7} \right] + \frac{3}{4} \left[ \frac{8(2^{n+1} - 11) - 8(2^{n-1})}{7} \right] - \frac{3}{4} x - 2$$

$$= \frac{8(2^{n+1} - 11) - 8(2^{n-1})}{7} - \frac{3}{4} x - 2$$

$$\geq 2^{k-1}\psi(P_n) + 2^{k-2} \left[ \frac{24(2^{n-1}) - 88}{7} \right] - x - 2$$

$$\geq 2^{k-1}\psi(P_n) - x - 2,$$

where the second inequality follows since  $\psi(P_n) \leq \frac{2^{n+1} + 3}{7}$ , the third inequality

follows since  $k \geq 5$  and  $\psi(P_n) \geq \frac{2^{n+1} - 2}{7}$ , and the sixth inequality follows

since  $n \geq 3$  and  $k \geq 5$ .

$$\text{That is, } \frac{3}{4} [\hat{f}(v_k) + \hat{f}(v_{k-1}) - 2] \geq 2^{k-1}\psi(P_n) - x - 2. \quad \text{---- (39)}$$

The inequality in (38) contradicts the inequality in (39).

Suppose, both  $\hat{f}(v_{k-1})$  and  $\hat{f}(v_k)$  are even, then from (37), we get

$$\frac{3}{4} [\hat{f}(v_{k-1}) + \hat{f}(v_k)] \leq 2^{k-1} [\psi(P_n) - x] - 1. \quad \text{---- (40)}$$

But, we have  $\hat{f}(v_k) + \hat{f}(v_{k-1}) \geq 2^{n-1}\psi(C_m) + \psi(P_{n-2}) - x$

$$= 2^{n-1} [2\psi(P_k) - |\alpha_k - 1|] + \psi(P_{n-2}) - x$$

$$\geq 2^{n-1} \left[ \frac{2(2^{k+1} - 1)}{7} - 1 \right] + \frac{2^{n-1} - 2}{7} - x$$

$$\geq 2^k \psi(P_n) - \frac{3(2^k)}{7} - \frac{8(2^{n-1})}{7} - \frac{2}{7} - x, \text{ where the second equality follows since}$$

$m=2k-1$ , the third inequality follows since  $\alpha_k = 2$  and  $\psi(P_n) \geq \frac{2^{n+1} - 2}{7}$ .

$$\begin{aligned}
\text{That is, } \frac{3}{4} \left[ \hat{f}(v_k) + \hat{f}(v_{k-1}) \right] &\geq \frac{3}{4} \left[ 2^k \psi(P_n) - \frac{3(2^k)}{7} - \frac{8(2^{n-1})}{7} - \frac{2}{7} - x \right] \\
&\geq 2^{k-1} \psi(P_n) + 2^{k-2} \left[ \frac{24(2^{n-1}) - 88}{7} \right] - x - 2 \\
&\geq 2^{k-1} \psi(P_n) - x - 1,
\end{aligned}$$

where the third inequality follows *since*  $n \geq 3$  and  $k \geq 5$ .

$$\text{That is, } \frac{3}{4} \left[ \hat{f}(v_k) + \hat{f}(v_{k-1}) \right] \geq 2^{k-1} \psi(P_n) - x - 1. \quad \text{---- (41)}$$

The inequality in (40) contradicts the inequality in (41).

**Subcase3 (b) :** If  $\hat{f}(v_{k-1}) + \hat{f}(v_k)$  is odd.

Without loss of generality, let  $\hat{f}(v_k)$  be odd. Then  $\hat{f}(v_{k-1})$  is even.

From (37), we get

$$\frac{3}{4} \left[ \hat{f}(v_{k-1}) + \hat{f}(v_k) \right] - \frac{5}{4} \leq 2^{k-1} [\psi(P_n) - x] - 2. \quad \text{---- (42)}$$

But, we have  $\hat{f}(v_k) + \hat{f}(v_{k-1}) \geq 2^{n-1} \psi(C_m) + \psi(P_{n-2}) - x$

$$= 2^{n-1} [2\psi(P_k) - |\alpha_k - 1|] + \psi(P_{n-2}) - x$$

$$\geq 2^k \psi(P_n) - \frac{3(2^k)}{7} - \frac{8(2^{n-1})}{7} - \frac{2}{7} - x,$$

where the second equality follows since  $m=2k-1$ . That is,

$$\frac{3}{4} \left[ \hat{f}(v_k) + \hat{f}(v_{k-1}) \right] - \frac{5}{4} \geq \frac{3}{4} \left[ 2^k \psi(P_n) - \frac{3(2^k)}{7} - \frac{8(2^{n-1})}{7} - \frac{2}{7} - x \right] - \frac{3}{4}x - \frac{5}{4}$$

$$\geq 2^{k-1}\psi(P_n) + 2^{k-2} \left[ \frac{24(2^{n-1}) - 88}{7} \right] - x - 2$$

$$\geq 2^{k-1}\psi(P_n) - x - 2,$$

where the third inequality follows since  $n > 2$  and  $k > 4$ .

$$\text{That is, } \frac{3}{4} \left[ \hat{f}(v_k) + \hat{f}(v_{k-1}) \right] - \frac{5}{4} \geq 2^{k-1}\psi(P_n) - x - 2. \text{ ---- (43)}$$

The inequality in (42) contradicts the inequality in (43).

From Subcase3 (a) and Subcase3 (b), we can always send  $\psi(P_n) - x$  pebbles to  $v_0$  at a cost of at most  $2^{k-1}[\psi(P_n) - x]$  pebbles. Thus, we cover dominate the path  $P_n$ . Now, we have to cover dominate  $C_m$ . In  $C_m$ , we have at least  $2^{n-1}\psi(C_m) + \psi(P_{n-2}) - x - 2^{k-1}[\psi(P_n) - x]$  pebbles. We need at most  $\psi(C_m)$  pebbles to cover dominate  $C_m$ . But,

$$\begin{aligned} & 2^{n-1}\psi(C_m) + \psi(P_{n-2}) - x - 2^{k-1}[\psi(P_n) - x] - \psi(C_m) \\ &= (2^{n-1} - 1)\psi(C_m) + \psi(P_{n-2}) - x - 2^{k-1}[\psi(P_n) - x] \\ &= (2^{n-1} - 1)[2\psi(P_k) - 1] - 2^{k-1}\psi(P_n) + \psi(P_{n-2}) + (2^{k-1} - 1)x \\ &\geq (2^{n-1} - 1) \left( \frac{2(2^{k+1} - 1)}{7} - 1 \right) - 2^{k-1} \left( \frac{2^{n+1} + 3}{7} \right) \\ &\geq 2^{k-1} \left[ \frac{2(2^n) - 11}{7} - \frac{9(2^{n-1} - 1)}{7(16)} \right] \\ &\geq 2^{k-1} \left[ \frac{55(2^{n-1}) - 165}{56} \right] > 0, \end{aligned}$$

where the second equality follows since  $m=2k-1$ , the third inequality follows since

$\alpha_k = 0$  and  $\psi(P_n) \leq \frac{2^{n+1} + 3}{7}$ , the fifth inequality follows since  $k \geq 5$ , and the sixth inequality follows *since  $n > 2$  and  $k > 4$ .*

Thus, we have enough pebbles to cover dominate  $C_m$  and hence we are done.

**Case3.2:**  $C_m$  contains  $y < \psi(C_m)$  pebbles.

This implies that,  $P_C$  contains  $2^{n-1}\psi(C_m) + \psi(P_{n-2}) - y$  pebbles. We use at most  $\psi(P_{n-1})$  pebbles to cover dominate  $P_C$ . Thus, we have at least  $2^{n-1}\psi(C_m) + \psi(P_{n-2}) - y - \psi(P_{n-1})$  pebbles in  $P_C$ . We need at most  $2^{n-1}[\psi(C_m) - y]$  pebbles from  $P_C$  to cover dominate the vertices of  $C_m$ . But,

$$\begin{aligned} & 2^{n-1}\psi(C_m) + \psi(P_{n-2}) - y - \psi(P_{n-1}) - 2^{n-1}[\psi(C_m) - y] \\ &= 2^{n-1}y + \psi(P_{n-2}) - y - \psi(P_{n-1}) \\ &\geq 2^{n-1} \left[ y - \frac{5 + 7y}{7(4)} - \frac{1}{7} \right] \\ &= 2^{n-1} \left[ \frac{21y - 9}{28} \right] > 0 \text{ if } y > 0, \end{aligned}$$

where the third inequality follows since  $n \geq 3$ . Thus, we can send  $\psi(C_m) - y$  pebbles to  $v_0$  and already  $C_m$  contains  $y$  pebbles implies that  $C_m$  contains  $\psi(C_m)$  pebbles and we are done.

So,  $\psi(L(m, n)) \leq 2^{n-1}\psi(C_m) + \psi(P_{n-2})$ .

Therefore,  $\psi(L(m, n)) = 2^{n-1}\psi(C_m) + \psi(P_{n-2})$ , if  $\alpha_k = 0$ .

$$\text{Hence, } \psi(L(m, n)) = \begin{cases} 2^{n-1}\psi(C_m) + \psi(P_{n-1}), & \text{if } \alpha_k = 1 \\ 2^{n-1}\psi(C_m) + \psi(P_{n-2}), & \text{if } \alpha_k = 0 \text{ or } 2 \end{cases}, \text{ where } m=2k-1 \text{ and}$$

$k-2 \equiv \alpha_k \pmod{3}$ . ■
